Abstract

Nowadays, many countries focus on developing clean energy such as photovoltaic (PV) as public awareness to degrade global warming has increased. However, PV power output is intermittently affected by weather conditions. Therefore, an advanced method is required to predict solar irradiance to obtain the precise PV output. This paper proposed a method called kernel extreme learning machine (K-ELM) used to forecast solar irradiance. Solar irradiance is very important in planning and operating of PV generation system to reduce procurement costs and improve the quality and safety of PV output to supply the load. The meteorological and solar irradiance data utilized for the K-ELM model were taken from the Lamongan and Muara Karang areas, Indonesia. The mean absolute error (MAE) criterion was employed to measure the accuracy of the proposed method. From the simulation results, the proposed K-ELM gained the best performance with 0.6669, and 0.791 for MAE in the Lamongan and Muara Karang regions, respectively. The ELM attained the second-best results for MAE with 0.807 and 0.8001. The LS-SVM obtained the third results for MAE with 1.2492 and 1.4315. The performance of SVM is the least with 4.9829 and 4.6398 for MAE in the Lamongan area and Muara Karang region, respectively.

Keywords: ELM, K-ELM, Photovoltaic, LS-SVM, SVM.

1. Introduction

Indonesia is the largest archipelago in the world that consists of 17.000 islands. Moreover, Indonesia has a population estimated at 269.54 million in 2019. Since Indonesia lies on the equator line, it has many advantages where almost all areas in this country receive direct solar light over the years. To date, this country is also endowed with rich natural resources included water, solar light, wind, geothermal, and other natural resources that are utilized as renewable energy (RE) sources [1]. The need and necessity of adequate energy harvested from natural resources for multiple goals have been revealed by most of the researchers in the global sector for decades. The blessing of solar light possessed by almost all areas in Indonesia had encouraged many researchers to develop an advanced RE technology as a solution to energy problems by harvesting energy from solar light, which is naturally replenished.

The advanced technology equipment that can harvest energy from solar light is called a photovoltaic (PV) panel, which collects solar light by utilizing solar cells as components of a PV panel and converting it into electric power. However, the power output of PV panels is highly dependent on solar irradiance. The solar irradiance process is a complex issue in nature because its magnitude is affected by the amount of various climatological and aerial components such as temperature, relative humidity, wind speed, and others [2, 3]. Moreover, the measurement of solar irradiance in nature is an arduous issue [4]. For decades, the empirical model was computed manually with several boundaries, including a case study of distinctive behaviours/patterns and diversity in the results, since the high stochasticity is included in actual data [5, 6]. The solar irradiance predictions are classified into three categories, which are; intra-hour prediction, short-term prediction, and long-term prediction. The intra-hour prediction has an hourly time horizon, while short-term prediction has a daily time horizon. The long-term prediction may have weeks or months or even years of time horizon. In a meantime, researchers in the energy sector are driven to construct a new method to forecast solar irradiance with high accuracy. The objective is to reduce the need for PV panels and the cost of installation economically and efficiently.

Since G. Mihalakakou has successfully proposed a neural network (NN) in order to forecast the solar irradiance [7], the prediction of solar irradiance based on an intelligent approach has gained the attention of many researchers in renewable energy fields. Numerous models to predict the solar irradiance using AI have been developed, such as adaptive neuro-fuzzy inference systems (ANFIS) [8], artificial neural network (ANN) [9], extreme learning machines (ELM) [10], long-short term memory (LSTM) [11], ANN-based corrective algorithm [12], hybrid evolutionary neural networks [13], hybrid artificial neural network and principal component analysis [14], convolutional long short-term memory [15], and deep neural networks [16]. In most cases, these approaches are very good for prediction, but some are more subjective in selecting parameters. In addition, these learning methods require an iterative process for their learning phase, so they are generally slow.

This paper proposes a kernel extreme learning machine (K-ELM) to forecast solar irradiance. The proposed method has some advantages in terms of fast learning speed and good generalization performance. Also, it has been applied in many fields such as condition monitoring [17], automatic heartbeat classification [18], prediction of COVID-19-pneumonia [19], prediction of heavy metals removal by biochar [20],

Journal of Engineering Science and Technology

fault diagnosis of aircraft engine [21], fault diagnosis of high-voltage circuit breakers [22], node localization in wireless sensor networks [23], and wind power prediction [24]. In this paper, the meteorological and solar irradiance datasets were collected from Lamongan and Muara Karang areas because both areas are coastal areas that have high solar irradiance over the years. The learning algorithm proposed in this study is compared to standard ELM, SVM, and LS-SVM.

2. Kernel Extreme Learning Machine

An ELM is a new kind of machine learning algorithm (MLA) [25]. The ELM model utilizes a feed-forward neural network with a single hidden layer. The input and output data are mapped quickly by this learning algorithm [26].

The ELM approach is employed to tackle the drawback of traditional neural networks (NN) [27] in terms of learning speed. A conventional NN requires a longer learning time since its network parameter is determined iteratively and more training samples must be included to obtain predictive output accurately [28].

The learning time of ELM is faster than the standard neural network because there is no iteration required in ELM. However, ELM has a weakness; that is trialand-error method employed to calculate neuron in the hidden layer of ELM. Furthermore, the hidden layer in the ELM method needs more neurons to provide better prediction results. Hence, the weighting parameter of ELM is selected randomly. The data from input layer to hidden layer of ELM is converted using the kernel function into higher dimensional feature subspaces. This method aims to transform a non-linear to a linear pattern. Additionally, it is utilized to reduce computational time for its learning process.

Given *N* data samples $\{(x_i, t_i) | x_i \in \mathbb{R}^n, t_i \in \mathbb{R}^m, i = 1, ..., N\}$, the mathematical model of ELM output with *M* hidden neurons is formulated using Eq. (1) [21],

$$y_{M}(x) = \sum_{i=1}^{M} \beta_{i} h_{i}(x) = h(x)\beta$$
(1)

The objective of ELM learning algorithm is to minimize the training error and the output weight at the same time as defined in Eq. (2) [24].

Minimize:
$$\|H\beta - T\|, \|\beta\|$$
.

The problem of Eq. (2) could be solved by using the Karush-Kuhn-Tucker optimality condition as defined in Eq. (3) [29].

$$\beta = H^T \left(\frac{1}{C} + HH^T\right)^{-1} T \tag{3}$$

The output of ELM in Eq. (4) is obtained by solving the formulation of β in Eq. (3) and substituted to Eq. (1) [29].

$$y(x) = h(x)H^{T} \left(\frac{1}{C} + HH^{T}\right)^{-1} T$$
(4)

The Mercer's condition utilized as kernel method which is defined in Eq. (5) is employed to overcome the unknown of feature mapping h(x) [20].

$$O = HH^T : m_{ij} = h(x_i)h(x_j) = \Omega(x_i, x_j)$$
(5)

Thus, the output function y(x) of K-ELM is represented in Eq. (6) [19].

Journal of Engineering Science and Technology April 2022, Vol. 17(2)

$$y(x) = \left[\Omega(x, x_1), K, \Omega(x, x_M)\right] \left(\frac{1}{C} + O\right)^{-1} T$$
 (6)

Many kernel functions satisfying the Mercer condition are available from the existing literature, such as the linear kernel, radial basis function kernel, polynomial kernel, Gaussian kernel, and exponential kernel. In this research work, a radial basis function (RBF) based kernel as defined in Eq. (7) is employed to test the performance of the proposed method [18].

$$\Omega(x, y) = \exp\left(\frac{\|x - y\|^2}{2\sigma^2}\right)$$
(7)

The K-ELM parameters (*C* and σ) have a great effect on the performance of the proposed algorithm. Therefore, these parameters should be properly chosen. The proposed learning algorithm proves to be more stable than conventional ELM and faster in process computing compared to SVM [30, 31]. The network scheme of K-ELM approach is depicted in Fig. 1.

Fig. 1. Network scheme of K-ELM method.

3. The Implementation of The Proposed Method

The features selected as input data of K-ELM as shown in Fig. 2 consist of temperature (C), wind speed (m/s), and humidity (%). As the predicted data or the output of K-ELM, solar irradiance (kWh/m²/day) data is utilized. The procedures for the solar irradiance forecasting model are classified into the training process and the testing phase.

Fig. 2. Proposed K-ELM scheme.

Journal of Engineering Science and Technology

The procedures for the training phase of the K-ELM method can be described as follow:

- i. Collect the data of wind speed, temperature, humidity, and solar irradiance.
- ii. Utilize wind speed, temperature, and humidity as input data for K-ELM. The output data of K-ELM is the predicted solar irradiance.
- iii. Normalize the real record value of input and output data of K-ELM to [-1,1]. The normalization of the datasets of wind speed, temperature, humidity, and solar irradiance is conducted because their real data records have a large value difference. The maximum and minimum values of wind speed, temperature, humidity, and solar irradiance are depicted in Table 1. The patterns of wind speed, temperature, humidity, and solar irradiance are shown in Figs. 3(a)-(b). The mathematical model for data normalization is described in Eq. (8).

$$X_n = 2(X_{p} - X_{p-min}) / (X_{p-max} - X_{p-min}) - 1$$
(8)

The minimum and maximum values $(X_{p-min} \text{ and } X_{p-max})$ of wind speed, temperature, humidity, and solar irradiance are illustrated in Table 1.

iv. Convert the input data of K-ELM using RBF kernel in Eq. (7) into high dimensional features.

$$\Omega(x, y) = \exp\left(\frac{\|x - y\|^2}{2\sigma^2}\right)$$

The kernel function is utilized to substitute the hidden neuron in the conventional ELM. RBF kernel is the most generalized form of kernelization and one of the most widely used kernels due to its similarity to the gaussian distribution.

- v. Set the parameters of K-ELM (i.e. C and σ).
- vi. Simulate the training stage using Eqs. (2)-(5) to produce the forecasted data of K-ELM in Eq. (6).
- vii. Denormalize the predicted result or output data of K-ELM to their exact values using Eq. (9). In this stage, the predicted result in the range of value [-1, 1] is transformed into their exact value.

$$X_d = 0.5(X_p + 1) \ge (X_{p,max} - X_{p,min}) + X_{p,min}$$
(9)

viii. Compute the accuracy of the predicted result. Statistical indicator namely mean absolute error (MAE) as depicted in Eq. (10) is employed for measuring the performance of the proposed method.

$$MAE = \frac{\sum_{i=1}^{N} |\hat{y}_i - y_i|}{N}$$
(10)

ix. If the MAE value is minimum, save the K-ELM parameters (i.e. *C* and σ) obtained from the training stage for the next step (testing process) and print out the predicted data of solar irradiance. Otherwise, go to step 5 until the minimum of MAE is obtained.

After the training phase has been conducted, the next procedure is the testing phase for the K-ELM approach to obtain the predicted value of solar irradiances. The workflow of the testing stage is described as follows:

Journal of Engineering Science and Technology

- i. Prepare the data for the testing phase (i.e. wind speed, temperature, humidity, and solar irradiance).
- ii. Use wind speed, temperature, and humidity as input data of K-ELM. Solar irradiance is employed as the forecasted data of K-ELM.
- iii. Utilize the K-ELM parameters (i.e. C and σ) obtained from the training stage.
- iv. Normalize the input and output data of K-ELM to [-1,1] using Eq. (8).
- v. Convert the input data of K-ELM using RBF kernel function Eq. (7) into high-dimensional features.
- vi. Compute the predicted data of K-ELM using Eq. (6).
- vii. Denormalize the predicted data of K-ELM from [-1, 1] to their exact value using Eq. (9).
- viii. Compute the degree of accuracy for K-ELM output based on MAE using Eq. (10).
- ix. Print out the predicted solar irradiance.

4. Results and Discussion

4.1. Forecasting data model and statistics for evaluation

To develop the proposed forecasting method, we utilized the real meteorological and solar irradiance data from Lamongan and Muara Karang areas, Indonesia, which were downloaded from the website of NASA prediction of worldwide energy resource [32]. The real data measurements were recorded from January 1st, 2013, to April 30th, 2019 (5 years and 4 months). The simulation process of this research work is conducted by AMD Ryzen 7 with 3.20 GHz. The proposed prediction method was written using MATLAB 2014a software [33]. In this research work, the dataset model was classified into the training and testing datasets. The meteorological and solar irradiance data aforementioned in section 3 were employed for training and testing phases. The datasets from January 1st, 2013, to December 31st, 2018 (2191 days) were included for the training process. The meteorological and solar irradiance data collected from January 1st, 2019, to April 30th, 2019 (120 days) were included as testing datasets. The patterns of meteorological and solar irradiance datasets of Lamongan and Muara Karang regions for 5 years and 4 months are shown in Fig. 3, while their maximum and minimum values are listed in Tables 1 and 2. The level of wind speed, temperature, humidity, and solar irradiance in Lamongan is higher than in Muara Karang.

4.2. Simulation results and discussions

Four prediction models based on machine learning, namely support vector machine (SVM) [34], least-square support vector machine (LS-SVM) [35], extreme learning machine (ELM) [36], and the proposed method called kernel extreme learning machine (K-ELM), were applied to the sample datasets. The comparisons of their performances in terms of MAE and speed of computation process are described in this section. The parameters of the four prediction models are provided in Table 3.

Table 3. Parameters of SVM, LS-SVM, ELM, and K-ELM.

SVM	LS-SVM	ELM	K-ELM
C = 0.0009	C = 0.0009	Hidden Neuron $= 50$	C = 10
$\sigma = 15$	$\sigma = 15$		σ = 50

The ELM learning algorithm utilized the RBF as the activation function, whereas SVM, LS-SVM, and K-ELM used the RBF as the kernel function. The real data record for solar irradiance data and the training process results are provided in Fig. 4. The highest errors in the training process produced by the K-ELM method were 3.97% and 4.12% for Lamongan and Muara Karang Areas respectively, as depicted in Fig. 5. The second-highest errors were obtained by ELM with 3.67% and 3.85%. The third-highest errors were obtained by LS-SVM with 1.44% and 0.29%. The lowest error values were obtained by the SVM approach with 0.47% and 0.13 for Lamongan and Muara Karang regions, respectively. These conditions occurred because the meteorological and solar irradiance variations in Lamongan and Muara Karang areas have non-linear characteristics and greatly affect the forecasting process.

The main objective of the training phase is to acquire the parameters of the proposed algorithm; thus, its parameter was utilized for the testing phase to test the efficacy of proposed method. The testing results of the forecaster model are depicted in Fig. 6. As shown in Fig. 7, the predictive accuracy criterion of the prediction scheme of the proposed method for the testing phase is better than those of ELM, LS-SVM, and SVM. The lowest MAE of Lamongan and Muara Karang areas is attained by proposed K-ELM with 0.6669, and 0.791, respectively. It is followed by ELM with 0.807 and 0.8001. The LS-SVM has MAE value of 1.2492 and 1.4315. The poorest result was found in SVM with 4.9829 and 4.6398 of MAE in Lamongan area and Muara Karang region, respectively.

Regarding the CPU time as described in Fig. 8(a)-(b) for the training phase, the proposed method has the best CPU time performance with 0.21 and 0.21 seconds for Lamongan and Muara Karang datasets, respectively. The second-best CPU time performance was obtained by ELM with 0.81 and 0.23 seconds. The third-best CPU time performance was attained by LS-SVM with 6.23 and 8.05 seconds. The poorest CPU time performance was obtained SVM with 18.17 and 20.56 seconds. The appropriately chosen data inputs of the learning algorithm play a key role in solar irradiation forecasting. When the feature selections are unrelated to the predicted response, the understanding of the relationship between them is disturbed and encourages long-term observation for the selection of features in the future. Simulation results have shown that the selection accuracy.

For example, the learning algorithm model employed in this work has a good, predicted result for the training phase but produced an unsatisfactory forecasted result in the testing process.

5. Conclusions

A new learning algorithm called K-ELM has been proposed to predict the solar irradiance in Lamongan and Muara Karang Areas, Indonesia in this paper. The simulation results show that the proposed approach has the lowest MAE value compared to those of the standard ELM, SVM, and LS-SVM for the testing phase. In terms of the learning speed, the proposed algorithm has the best performance compared to the other learning algorithms examined in this paper. The proposed algorithm achieves a more stable ability and better generalization performance than ELM, SVM, and LS-SVM algorithms in terms of learning speed. For the further study in the future, the application of a meta-heuristic approach to improving the performance of the learning algorithm are not optimized.

Spaces	∑ Important	Dear author(s),				
Cr.	▷ Sent	Thank you for submitting your research paper to The Jour	urnal of Engineering Science and Technology (JESTEC).			
Meet	Drafts 114	However, your submission to JESTEC is incomplete with	vithout satisfying other documents.			
		Please refer to the <u>attach files</u> to follow the guidelines for All attached document in this incomplete submission will ?	r author to prepare a complete submission to JESTEC. Requirements for each document must b NOT be saved in JESTEC system. Hence, a new submission is required by sending again with all	se fulfilled as clearly stated in the guidelines. I the 5 documents together with satisfied requirements in one email	а.	
	Social 585					
	i Updates 1,117	We would also like to draw your attention that: 1) Publication fee in JESTEC is USD300	per article.			
	Forums 210	 Upon the full acceptance of your paper 	r, publication fee in amount of USD300 must be paid before the article is published in	the journal website. An official invoice will be sent with all r	required details to make safe payment.	
	Promotions 971	 The number of pages per article should 	ld be minimum 8 pages and maximum 20 pages.			
	✓ More	We do hope to receive your complete resubmission soon.	L			
	Labels .	Thank you for cooperation.				
	Labels +	Best regards.
